

CSE-303: COMPUTER GRAPHICS

PROFESSOR DR. SANJIT KUMAR SAHA

DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

JAHANGIRNAGAR UNIVERSITY, SAVAR, DHAKA

2D VIEWING AND CLIPPING

INTRODUCTION

Window

- A world-coordinate area selected for display
- Define what is to be viewed

View port

- An area on a display device to which a window is mapped
- Define where it is to be displayed
- Define within the unit square
- The unit square is mapped to the display area for the particular output device in use at that time

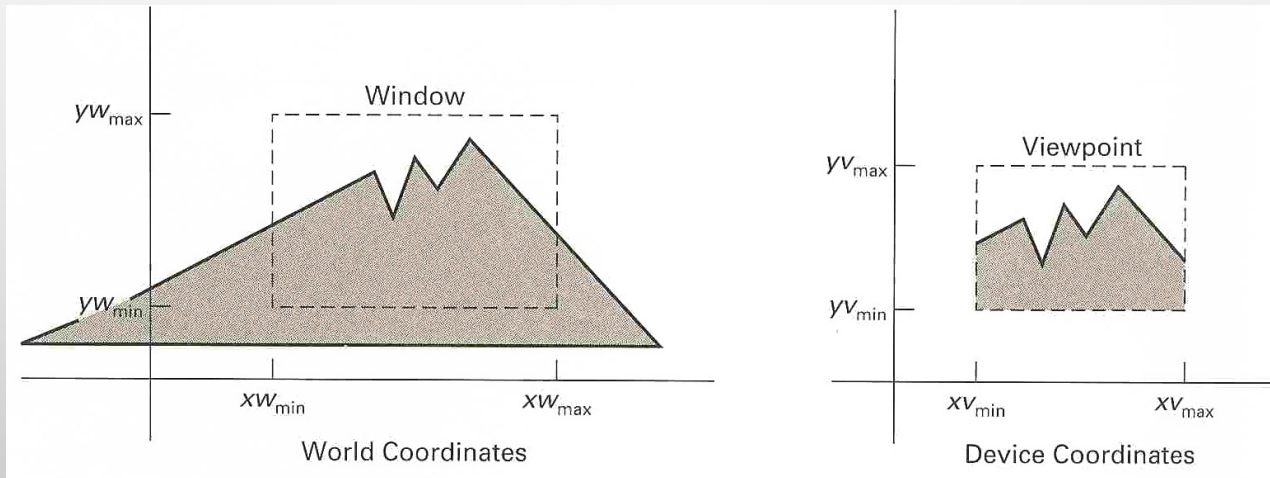

Windows & viewport

- Be rectangles in standard position, with the rectangle edges parallel to the coordinate axes

INTRODUCTION

Viewing transformation

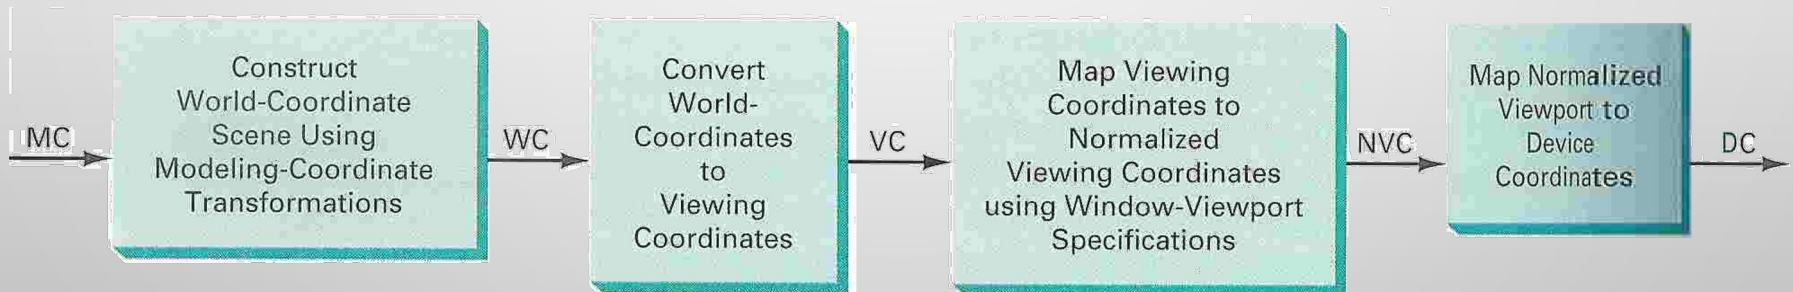

- The mapping of a part of a world-coordinate scene to device coordinates
- 2D viewing transformation = window-to-viewport, windowing transformation

INTRODUCTION

Viewing-transformation in several steps

- Construct the world-coordinate scene
- Transform descriptions in world coordinates to viewing coordinates
- Map the viewing-coordinate description of the scene to normalized coordinates
- Transfer to device coordinates

INTRODUCTION

Viewing-transformation

- By changing the position of the viewport
 - Can view objects at different positions on the display area of an output device
- By varying the size of viewports
 - Can change the size and proportions of displayed objects
 - Zooming effects

VIEWING COORDINATE REFERENCE FRAME

- The composite 2D transformation to convert world coordinates to viewing coordinates

$$M_{WC,VC} = R \cdot T$$

WINDOW-TO-VIEWPORT COORDINATE TRANSFORMATION

- **Transfer to the viewing reference frame**
 - Choose the window extents in viewing coordinate
 - Select the viewport limits in normalized coordinate
- **To maintain the same relative placement in the viewport as in the window**

$$\frac{xv - xv_{\min}}{xv_{\max} - xv_{\min}} = \frac{xw - xw_{\min}}{xw_{\max} - xw_{\min}}$$

$$\frac{yv - yv_{\min}}{yv_{\max} - yv_{\min}} = \frac{yw - yw_{\min}}{yw_{\max} - yw_{\min}}$$

- **Thus**

$$xv = xv_{\min} + (xw - xw_{\min})sx$$

$$yv = yv_{\min} + (yw - yw_{\min})sy$$

where,

$$sx = \frac{xv_{\max} - xv_{\min}}{xw_{\max} - xw_{\min}}$$

$$sy = \frac{yv_{\max} - yv_{\min}}{yw_{\max} - yw_{\min}}$$

WINDOW-TO-VIEWPORT COORDINATE TRANSFORMATION

- Eight coordinate values that define the window and the viewport are just constants.
- Express these two formulas for computing (vx,vy) from (wx,wy) in terms of a translate-scale-translate transformation N.

$$\begin{pmatrix} vx \\ vy \\ 1 \end{pmatrix} = \begin{pmatrix} wx \\ wy \\ 1 \end{pmatrix}$$

• Where

$$N = \begin{bmatrix} 1 & 0 & xv_{\min} \\ 0 & 1 & yv_{\min} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \frac{xv_{\max} - xv_{\min}}{xw_{\max} - xw_{\min}} & 0 & 0 \\ 0 & \frac{yv_{\max} - yv_{\min}}{yw_{\max} - yw_{\min}} & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & -xw_{\min} \\ 0 & 1 & -yw_{\min} \\ 0 & 0 & 1 \end{bmatrix}$$

CLIPPING OPERATIONS

- Clipping
 - Any procedure that identifies those portions of a picture that are either inside or outside of a specified region of space
- Applied in world coordinates
- Adapting primitive types
 - Point
 - Line
 - Area (or polygons)
 - Curve

POINT CLIPPING

- Assuming that the clip window is a rectangle in standard position
- For a clipping rectangle in standard position, we save a 2-D point $p(x,y)$ for display if the following inequalities are satisfied:

$$x_{\min} \leq x \leq x_{\max}$$

$$y_{\min} \leq y \leq y_{\max}$$

- If any one of these four inequalities is not satisfied, the point is clipped (not saved for display)
- Where $x_{\min}, x_{\max}, y_{\min}, y_{\max}$ define the clipping window.

Point Clipping

If $P(x,y)$ is inside the window?

$$xw_{\min} \leq x \leq xw_{\max}$$

$$yw_{\min} \leq y \leq yw_{\max}$$

LINE CLIPPING

- **Line clipping procedure**

- Test a given line segment to determine whether it lies completely inside the clipping window
- If it doesn't, we try to determine whether it lies completely outside the window
- If we can't identify a line as completely inside or completely outside, we must perform intersection calculations with one or more clipping boundaries

LINE CLIPPING

- Checking the line endpoints \Rightarrow inside-outside test

- Line clipping
 - Cohen-Sutherland line clipping
 - Liang-Barsky line clipping

COHEN-SUTHERLAND ALGORITHM

- Divide the line clipping process into two phases:
 - Identify those lines which intersect the clipping window and so need to be clipped.
 - Perform the clipping
- All lines fall into one of the following clipping categories:
 - Visible: both end points of the line lie within the window.
 - Not visible: the line definitely lies outside the window. This will occur if the line from (x_1, y_1) to (x_2, y_2) satisfies any one of the following inequalities:

$$x_1, x_2 > x_{\max} \quad y_1, y_2 > y_{\max}$$

$$x_1, x_2 < x_{\min} \quad y_1, y_2 < y_{\min}$$

- Clipping candidate: the line is in neither category 1 nor 2

COHEN-SUTHERLAND ALGORITHM

Find the part of a line inside the clip window

P_3P_4 is in category 1(Visible)

P_1P_2 is in category 2(Not Visible)

$P_5P_6, P_7P_8, P_9P_{10}$ is in category 3(Clipping candidate)

COHEN-SUTHERLAND ALGORITHM

COHEN-SUTHERLAND ALGORITHM

- Assign a four-bit pattern (Region Code) to each endpoint of the given segment. The code is determined according to which of the following nine regions of the plane the endpoint lies in.

- Of course, a point with code 0000 is inside the window.

COHEN-SUTHERLAND ALGORITHM

COHEN-SUTHERLAND ALGORITHM

- If both endpoint codes are 0000 → the line segment is visible (inside).
- The logical **and** of the two endpoint codes
 - not completely 0000 → the line segment is not visible (outside)
 - Completely 0000 → the line segment **maybe** inside (and outside)
- Lines that cannot be identified as being completely inside or completely outside a clipping window are then **checked for intersection** with the window border lines.

COHEN-SUTHERLAND ALGORITHM

- Consider code of an end point

- If bit 1 is 1, intersect with line $y = y_{\max}$
- If bit 2 is 1, intersect with line $y = y_{\min}$
- If bit 3 is 1, intersect with line $x = x_{\max}$
- If bit 4 is 1, intersect with line $x = x_{\min}$

- consider line CD.

- If endpoint c is chosen, then the bottom boundary line $y=y_{\min}$ is selected for computing intersection
- If endpoint D is chosen, then either the top boundary line $y=y_{\max}$ or the right boundary line $x=x_{\max}$ is used.
- The coordinates of the intersection point are:
 - $Y = y_0 + m(x-x_0)$
 - $X = x_{\max}$ or x_{\min} if the boundary line is vertical or
 - $X = x_0 + 1/m(y-y_0) x_{\min}$ if the boundary line is horizontal
 - $Y = y_{\max}$ or y_{\min} , where $m = \frac{y_{end} - y_0}{x_{end} - x_0}$

COHEN-SUTHERLAND ALGORITHM

- Replace endpoint (x_1, y_1) with the intersection point (x_i, y_i) , effectively eliminating the portion of the original line that is on the outside of the selected window boundary.
- The new endpoint is then assigned an updated region code and the clipped line re-categorized and handled in the same way.
- This iterative process terminates when we finally reach a clipped line that belongs to either category 1 (visible) or category 2 (not visible).

COHEN-SUTHERLAND LINE CLIPPING

- Use simple tests to classify easy cases first

COHEN-SUTHERLAND LINE CLIPPING

- Classify some lines quickly by AND of bit codes representing regions of two endpoints (must be 0)

COHEN-SUTHERLAND LINE CLIPPING

- Classify some lines quickly by AND of bit codes representing regions of two endpoints (must be 0)

COHEN-SUTHERLAND LINE CLIPPING

- Classify some lines quickly by AND of bit codes representing regions of two endpoints (must be 0)

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING

- Compute intersections with window boundary for lines that can't be classified quickly

COHEN-SUTHERLAND LINE CLIPPING
